#### Abstract

This paper shows a clear distinction between Spectral Analysis and Harmonic Analysis and highlights what is common amongst these two terms. The distinction and commonalities are illustrated using the data from sales of cement obtained from a sales record. The work identified the role of spectral analysis as that of showing the periods /wavelengths having containing more energy with the sine and cosine components but without stating whether the components are significant or not. Spectral analysis helps to identify hidden periodicities but does not form the model equation. Harmonic analysis on the other hand makes use of the periods with higher energies identified by the spectral analysis to form a model equation, it also shows whether the frequencies are significant or not by displaying the $t$-values for each $k^{\text {th }}$ harmonic value used to form the model equation. From the giving data, harmonic analysis makes predictions/forecasts, performs model parameter estimation, Analysis of variance, displays the asymptotic correlation matrix of parameters. In harmonic analysis, the graphs of errors against time and against the predicted values are also plotted.

Keywords: Harmonic analysis, spectral analysis, period, wavelength, model, forecasting.

### 1.0 Introduction

Most text book writers take spectral analysis as harmonic analysis and vice versa.Brillinger(2001) considered harmonic analysis as a tool for search of hidden periodicities. But Rebeca (2004) unlike most of the other authors explained that harmonic analysis works on the assumption that the modeler already knows the period, one can easily set up a regression equation and find out the amplitude, the phase and the mean of the signal. In the analysis of time series data, etc, it is often necessary to identify the periodicities in the data by spectral analysis which is concerned with the partition of the variation in a time series between the components at different frequencies or periods. In spectral analysis, if the data is not stationary it should first be detrended by fitting a proper curve to the data set and then using that to remove the trend. But if the data does not show obvious trend, one can then remove the mean and proceed to carry out spectral analysis. Differencing can also be employed to make the data set stationary. The Number Cruncher Statistical System (NCSS) has six portions on carrying out spectral analysis as shown in Table 1.

Table 1. Fourier Analysis ( $\mathrm{p}, \mathrm{q}, \mathrm{s}, \mathrm{t}, \mathrm{u}$ )

| (a) | (b) | (c | (d) | (e) | (f) |
| :---: | :---: | :--- | :--- | :--- | :--- |
| Frequencies | Wavelength | Period | Cosine $\left(a_{k}\right)$ | Sine $\left(b_{k}\right)$ | Spectrum |

But we recommend a seven- column portion as given in Table 2. so as to make room for the harmonic number (k)

Table 2. Fourier Analysis ( $p, q, s, t, u$ )

| $(\mathrm{a})$ | (b) | (c) | (d) | (e) | (g) |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Harmonics <br> $(\mathrm{k})$ | Frequencies(f) <br> $\left(\mathrm{f}_{k}\right)$ | Wavelength <br> $\mathrm{L}=\frac{N}{f}$ | Period | Cosine $\left(a_{k}\right)$ | - Sine $\left(b_{k}\right)$ | Spectrum |

Where,

$$
\begin{aligned}
& a_{k}=\frac{N}{2} * \sum_{k=1}^{\frac{L}{2}} y_{k} * \operatorname{Cos}\left(\theta_{k}\right) \\
& b_{k}=\frac{N}{2} * \sum_{k=1}^{\frac{L}{2}} y_{k} * \operatorname{Sin}\left(\theta_{k}\right)
\end{aligned}
$$

The data points are: $Y_{k}=\left(y_{1}, y_{2}, \ldots y_{n}\right)$
$\mathrm{K}=\frac{N}{2}$ for even number of data points, or $\frac{N-1}{2}$ for odd numbered data points.
When the data has a clear seasonal length, $L$, then
$\mathrm{k}=\frac{N}{L}$
The column headed spectrum shows the amount of energy or proportion of the contribution of each of the frequencies to the variance of the series.

Spectral analysis also makes the plots of the spectrum against each of the following items: time, wavelength, and, frequency

It is the spectral analysis that helps one to begin to think of the frequencies /wavelength that will enter into the model building process. Spectral analysis does not give the model, the phase angels and makes no prediction from the data.

In Harmonic analysis, one uses the frequencies identified from spectral analysis to form a model and harmonic analysis gives about eight different specific results as shown through Table 3 to Table 10.Fourier analysis is part of harmonic analysis, but in literature, most authors' mistake spectral analysis for harmonic analysis and most statistical software's also fall into the same misconception, but the use of the Number Cruncher Statistical System(NCSS), illustrates the role of either spectral analysis or harmonic analysis.

## 2. Statement of the problem.

In order to carry out a Fourier series analysis of any time series data, one must use the periodic components and time series data are seasonal or periodic and more often than not these periodicities are hidden. To unmask the hidden periodic components spectral analysis needs to be performed on the data set. Results from spectral analysis are then used to perform harmonic analysis through Fourier series analysis. There is therefore the need to make a clear distinction between spectral analysis and harmonic analysis in the Fourier analysis of time series data .

## 3. Aim

The aim of this study is to show the difference between spectral analysis and harmonic analysis in the analysis of time series data through a worked example using the Number Cruncher Statistical System.

## 4. Data Source and Materials Used.

The data set used in this work is the sales of bags of cement obtained from Ogwumabiri Market in Obowo Local Government Area of Imo State ,Nigeria and this is shown graphically in Figure 1 and the data set is shown in Table 1.The software used to do the analysis of date was the Number Cruncher Statistical System (NCCS2019) by Chris Hintz

5. Methodology

The data was first subjected to outlier test by the Grubbs test for outliers and the (NCSS 2019) found are no outliers.
51. Spectral Analysis

The software (NCSS2019) gave the spectral analysis results in two folds as will be shown in the sequel, it removed the trend as the data displayed in Table 1. depicts trending pattern. Note that if the data has no trend, the mean will be then removed from the data.The spectral plots are displayed in figures 2 and 3.

Fig. 2 .Plot of Periodogram against Frequency.

The plots of periodogram against frequency and that of periodogram against wavelengths are shown as Fig.2. and Fig. 3 and each of them show that there is only one dominant frequency at the harmonic number $\mathrm{k}=7$, with a frequency $\mathrm{f}=0.514054$ and wavelength 12.22281 . .

Table 2 shows the Fourier analysis result indicating the highest energy content at the $7^{\text {th }}$ harmonic $\mathrm{k}=7$ as $2.15 * 10^{7}$,the cosine component is -1541.93 and the sine component is -681.31

$$
\begin{array}{lllllll}
7 & 0.514054 & 12.22281 & 2.15 \mathrm{E}+07 & -1541.93 & -681.31 & 1.00 \mathrm{E}+33
\end{array}
$$

Spectral analysis results end after identification of wavelength, sine term, cosine term, period, and the spectrum. Using the NCSS, the harmonic numbers are not shown, hence we invoke the use of Excel to supplement the analysis in order to add the harmonic numbers as shown in Colum (a) in Table 1.

## The use of Harmonic analysis

Harmonic analysis is used to obtain the various section as explained here under.

Below are the steps involved in carrying out the harmonic analysis:

After performing the spectral analysis as discussed above, when the harmonic section of the NCSS2019 was now employed the following results were obtained:

Table 3.Run Summary Section -

| Item | Value | Item | Value |
| :--- | :---: | :--- | ---: |
| Dependent <br> Variable | Yt | Total Rows | 156 |
|  |  | Rows with Missing |  |
| Time Variable | t | Values | 60 |
| $\mathrm{R}^{2}$ | 0.96 | Rows Used | 96 |

Estimated Model
$\mathrm{Ft}=307.273+(4.317) * \mathrm{t}-15.1354)^{*} \mathrm{SIN}((0.517 * \mathrm{t}+66.998 * \operatorname{COS}(0.517 \mathrm{t}))$
The amplitude value of 68.68638 is obtained from the squares of the sine and cosine coefficients Of;
$68.68638=\sqrt{(-15.1354)^{2}+(66.998)^{2}}$

Table 4.Regression Coefficients Section

|  | Regression | Standard | T- <br> Statistic to |  | Upper95\% |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
|  |  |  |  |  | Conf. |
| Independent | Coefficient | Error | Test | Prob | Limit |

Fig.3.Predicted and Actual values Values against Time

Fig.4.Graph of Residuals against Time
The plot of residuals against time shown in Fig. 4 demonstrates that the errors are random in nature, and the plot of actual and predicted values against time shown in Fig.3. is an evidence that that the actual and predicted values are reasonably close to each other.

| 9 | -0.075281 | 20 | -0.000654 | 30 | -0.124178 |  | 40 | -0.092858 |

Significant if |Correlation|> 0.204124
The results from both Tables 5 and 6 show that that the PAC F, and ACF have absolutes values that are less than the table value of 0.204124 as indicated by the software. This further confirms the adequacy of the adopted model. The plots of ACF and PACF shown in Figures 4 and 5 each did not exhibit spike at any lag,demonstrating that the correct model has been obtained.

Conclusion.
The paper has explained briefly the difference between spectral analysis and harmonic analysis given the results in each case using an example. It has also shown that to carry out harmonic analysis, spectral analysis must be performed to obtain significant frequency that will be used to get an appropriate model.
